42 **Introduction**
43

44 This document is a first draft technical specification for review by the ebXML Plenary.
45 Comments are welcome. When registering your comment, please provide the following
46 information:

- 47 ➤ Your name,
- 48 ➤ Your email address,
- 49 ➤ The document line number(s) associated with your comment,
- 50 ➤ Your comment,
- 51 ➤ Rationale for the comment, and,
- 52 ➤ Your recommended action for resolution of the issue or any recommended document
53 add/change/delete modifications.

54
55 Please e-mail comments to Marcia McLure, marcia.mclure@mmiec.com within two weeks
56 following the official posting date of May 26, 2000.
57

58 This document includes the following sections:
59

- 60 The ebXML Business Process Metamodel Class Diagram
- 61 Metamodel Sub-groupings
- 62 Descriptions of the Metamodel Sub-groupings
- 63 Metamodel Sub-grouping Class Diagrams
- 64 Class Definitions
- 65 Scenarios for the Use of the ebXML Business Process Metamodel
- 66 Automobile Component Procurement Example
- 67 Issues

68
69
70 Suggestions for document improvement are welcome. Thank you, in advance for your
71 comments.

The ebXML Business Process Metamodel

This is the ebXML business process metamodel that more fully defines the contract/commitment section. This ebXML business process metamodel also enables re-usability of process definitions. We refer to this state of the metamodel as Version 1.0.

The model consists of the following logical sub-groupings:

1. Resources and Contracts (color coded in blue),
2. Markets and Communities (color coded in green),
3. Business Processes and Rules (color coded in yellow),
4. Business Service Interfaces and Communication (color coded in purple), and the
5. Information Model (color coded in brown).

The ebXML Business Process Metamodel

Metamodel Sub-groupings

The metamodel consists of the following logical sub-groupings:

1. Resources and Contracts

This is a high level economic model, adapted from REA (Resources, Events, and Agents). It creates a very useful anchor point for the ebXML model, and establishes a pattern for how economic events should be transacted using this model.

2. Markets and Communities

This is the part of the model that allows organizations to register themselves relative to the markets they perform in and the types of services they offer. This aligns with the first four of the seven layers of the eCO framework. Once a number of organizations have registered themselves, other organizations can start discovering new business partners by navigating among the layers of the markets and communities submodel.

3. Business Processes and Rules

This is the part of the model that describes the actual business processes that support the services offered by a given organization. It also describes the interactions required between the partners in order to obtain/perform the services offered.

4. Business Service Interfaces and Communication

This is the part of the model that describes the ‘interface’ that the partners expose, against which the ‘opposing’ partner can interact, typically by sending business signals consisting of business documents. Document is a broad term that covers both complete documents in the traditional sense, i.e. a sales order, but also descriptions of business events relevant to the service obtained/performed.

Class Definitions

Definitions of each of the classes are as follows:

Agent.

An **agent** is a particular kind of business process interface that represents an individual.

Agreement

An **agreement** is an arrangement between two parties that specifies in advance the conditions under which they will trade (terms of shipment, terms of payment, expectations of quotations and pricing, etc.) An agreement does not imply specific economic commitments.

Agreement Type

An **agreement Type** is the abstract classification of different types of agreements. Examples might include front-end agreements and yearly contracts.

Business Activity.

A **business activity** is used to represent the state of the business process of one of the partners. For instance the requester is either in the state of sending the request, in the state of waiting for the response, or in the state of receiving (and processing) the response.

Business Document.

A **business document** is the description of a particular entity within a business, or the description of an agreement between organizations, or the description of a business event. The document is never the 'real' thing, just a description of it. A business document is the central component of any information exchange among partner roles.

Business Event

A **business event** is an activity that a business decision- maker needs to monitor or evaluate. In most cases, a business event is performed with the objective of making progress toward a specific business goal within the context of a business process. However, some business events simply exchange or synchronize information between parties. Business event examples might include “obtain a quote” or “make an engineering change.”

Business Process

A **business process** is a collection of business events that are required to achieve a business goal. Normally, such objectives imply the execution of a business transaction or a related set of business transactions that are intended to accomplish a value-added entrepreneurial purpose.

Business Process Definition

A **business process definition** specifies the choreography of business transactions needed to complete a business process.

224 **Business Process Interface.**

225 A **business process interface** is the definition of how to interact with one partner role in order to
226 make him/her perform a desired service. For example, a partner role can expose a business
227 process interface for 'quotation service'. It will describe precisely what kind of business signal
228 (i.e. message) you need to send, what you will get back, and what you may expect to have
229 happen as a result of the exchange.

230

231 **Business Rule.**

232 A **business rule** is a very generic term to describe rules that govern how we conduct business. In
233 this context a business rule is a rule that guides and constrains the execution of steps within a
234 business process.

235

236 **Business Signal.**

237 A **business signal** is a message sent between the business process interfaces of two partner roles.
238 A business signal fulfills the information flow requirements between request activity and
239 response activity. A business signal contains business documents(s).

240

241

242 **Business Transaction**

243 A **business transaction** is a logical unit of business conducted by two or more parties. The
244 community, the partners, and the process, are all in a definable, and self-reliant state prior to the
245 business transaction, and in a new definable, and self-reliant state after the business transaction.
246 In other words if you are still 'waiting' for your business partner's response or reaction, the
247 business transaction has not completed. A business transaction in our model is reflected as the
248 required exchange or series of exchanges of information between two (or more) partner roles in
249 order to complete the transaction. For example, the exchange could consist of a request for quote
250 and the return either of the actual quote, or of the confirmation that the request had been
251 received. It would not make sense to have the transaction (interaction) consist of the request only

252

253 **Commitment**

254 A **commitment** is an obligation to perform an economic event at some future point in time.
255 Commitment are fulfilled or executed by economic events.

256

257 **Community.**

258 A **community** is a collection of parties that have formed a set of mutual partnerships in support
259 of a shared goal. Within a community a party takes on a particular role, and is now distinguished
260 as being a 'partner' as opposed to just a 'party'. Communities often, but not always, form as
261 subsets of markets. What communities have in common are shared interests and shared
262 processes. Examples of communities are: A given company's entire supply chain, An alliance or
263 joint venture of a number of companies to collaborate to offer complete solutions, A company
264 and all its customers.

265

266 **Contract**

267 A **contract** is a mutual arrangement between parties that some actual economic exchanges will
268 occur in the future. Contracts can have recursive relationships with other contracts, for example,
269 yearly contracts with monthly releases and weekly or daily shipping schedules. Contracts are

270 containers for collections of commitments. For example, a purchase order is a contract wherein
271 the line items are commitments.

272

273

274 **Contract Type.**

275 A **contract type** is the abstract classification or definition of a contract. Examples might be
276 service contracts, orders, and committed-plans.

277 As in other type objects, contract types are not just categories, they can also define the rules and
278 processes governing contracts of the type.

279

280

281 **Dictionary.**

282 The **dictionary** should contain data types, re-usable components, and the templates (DTD's) of
283 the business documents, but not the documents themselves.

284

285

286 **Document Envelope.**

287 A **document envelope** is the wrapper of an information flow between partner roles.

288 It is not completely within the scope of the business process project team, rather it belongs to the
289 transport project team, but we need to all have a common agreement on the business aspects and
290 core component aspects of what goes in the envelope.

291

292 **Duality.**

293 **Duality** is a relationship between Economic Events, where one is the legal or economic
294 consideration of the other. Examples include a payment for a product or service.

295

296 **Economic Event**

297 An **economic event** is the transfer of control of an Economic Resource from one party to another
298 party. Examples would include sale, cash-payment, shipment, and lease.

299

300 **Economic Resource**

301 An **economic resource** is a quantity of something of value that is under the control of an
302 enterprise. Examples are cash, inventory, labor service and machine service.

303

304 **Economic Resource Type**

305 An **economic resource type** is the abstract classification or definition of an Economic Resource.
306 For example, in an ERP system, ItemMaster or ProductMaster would represent the Economic
307 Resource Type that abstractly defines an Inventory Item or Product. Economic Resource Types
308 may have recursive relationships, so that for example broad classifications like "product" could
309 group smaller classifications like "product family", which in turn could have as members the
310 specific "product masters" with SKU numbers.

311

312 **Fundamental Information Entity.**

313 A **fundamental information entity** is in essence a data type. In business contexts we might need
314 many more 'data types' with business semantics beyond the standard data types of 'int', 'float' etc.

315

316

317 **Information Entity.**

318 An **information entity** is a primitive or complex data structure. We haven't defined this yet, but
319 it may be that the difference between a data structure and an information entity is that the
320 information entity also contains business rules about the data.

321

322 **Information Flow.**

323 An **information flow** is a flow of information between partner roles, related to a specific set of
324 business activities within a specific business transaction. Often the information flow will specify
325 a particular business document to be exchanged between the partners before the interaction or the
326 general process can proceed.

327

328

329 **Market.**

330 A **market** is a 'meeting place' where organizations and individuals can exchange services or
331 products. A market is defined in terms of the types of services and products that are likely to be
332 exchanged. The "Yellow Pages" in a telephone book is an example of classifications of products
333 and services, e.g. 'Legal Services', or 'Air condition products'. A person can then anticipate the
334 existence of a 'Legal Services' market and an 'Air Conditioning' market.

335

336 **Partner.**

337 A **partner** is a participant in a community. It is defined in terms of it's generic partner type and
338 its particular partner role(s) within processes within the community.

339

340 **Partner Role**

341 A **partner role** is the role a party plays in a specific business transaction.

342

343 **Partner Type.**

344 A **partner type** is a broad classification of the kind of role an organization or individual is able
345 to play within a community. Examples would be 'supplier', 'agent', 'consultant', 'administrator',
346 'consumer'.

347

348 **Party**

349 A **party** is any organization or individual that participates in exchanges of products or services in
350 one or more markets. A party is established first as an absolute entity and then in terms of the
351 roles it plays in a market and in terms of the role it plays in a business transaction.

352

353 **Party Role** (Party Role is shown only as "Role" in the diagram.)

354 A **party role** is the role a party plays within a given market. Examples would be 'manufacturer',
355 'whole-saler', 'consultancy', 'logistics'. A party can have one or more roles within each market.

356

357 **Party Type.**

358 A **party type** is a broad classification of the kind of organization or individual. Examples are
359 'University', 'Corporation', 'Individual', 'Government'.

360

361

362

363

364 **Process Category.**

365 A **process category** is a broad classification of business processes. At a macro level this
366 classification could be like the "Yellow Pages" classification of services. At a finer level,
367 processes could be classified to more functional groupings such as 'quotation', 'scheduling',
368 The metamodel does not constrain the kinds of classification of processes.

369

370 **Resource Catalog**

371 A **resource** catalog is basically a navigable guide to offered products and services (Economic
372 Resource Types). It is the market equivalence of a company's product catalog. It would be
373 intended for narrowing down the particular kind of product or service you are looking for,
374 hopefully leaving you with multiple possible sources for that product or service.

375

376

377 **Service.**

378 A **service** is a particular kind of business process interface that represents an organization.

379

380 **Step.**

381 A **step** is a decomposition of a process that has a dependency on another decomposition. That
382 dependence could be a predetermined sequence, or it could be otherwise determined through
383 simple or complex business rules. A step is always either an action taken by a single partner role
384 or an interaction among partner roles.

405

406
407
408 **Scenarios for Use of the ebXML Business Process Metamodel.**
409

410 The objective of ebXML is to “create a single global electronic market” that enables
411 organizations to find each other and conduct business together through the exchange of
412 information in the form of XML based business documents.
413

414 From this statement we can glean the following layers of importance to the Business Process
415 Metamodel:
416

417 It must support the definition of a “market”, the definition of processes for “conducting
418 business”, the definition of required “exchanges of information”, and the definition of the
419 “business documents” themselves.
420

421 Therefore the following LAYERS of the business process must be supported by the metamodel:
422

- 423 A. Market (for categorizing and organizing parties and their processes/services)
 - 424 B. Business Process (for conducting business)
 - 425 C. Information Exchange (in support of a business process)
 - 426 D. Business Document (for structuring information)
- 427
428

429 Note: There is an alignment of these layers to the packages of the metamodel.

430 The alignment is as follows:

- 431 • The market layer uses the ‘Markets and Communities’ package and the resource part
432 of the “Resources and Contracts” package.
- 433 • The Business Process layer uses the “Business Process and Rules” package and the
434 “Resources and Contracts” package.
- 435 • The “Information Exchange” layer uses the “Information Flow and Communication”
436 package.
- 437 • The “Business Document” layer uses the business document and information entity
438 part of the “Information Flow and Communication” package.
439

440 We also divide the scenarios for usage of the metamodel into the following ‘STAGES’:
441

- 442 1. Designing/Describing markets, business processes, information exchanges and business
443 documents.
 - 444 2. Implement system to execute in conformance with described business processes,
445 information exchanges and business documents
 - 446 3. Registering markets, business processes, information exchanges and business documents.
 - 447 4. Discovering markets, business processes, information exchanges and business
448 documents.
 - 449 5. Actual execution of a business process through the exchange of business documents.
450
- 451
452

453
 454 So we can organize the scenarios as follows:
 455
 456

	1. Design/Describe	2. Implementation	3. Register	4. Discover	5. Execution
A: Market	Market-Design	N/A	Market-Registration	Market-Discovery.	N/A
B: Business Process	Process-Design	Process-Implementation	Process-Registration	Process-Discovery	Process-Execution
C: Information Exchange	Exchange-Design	Exchange-Implementation	Exchange-Registration	Exchange-Discovery	Exchange-Execution
D: Business Document	Document-Design	Document-Implementation	Document-Registration	Document-Discovery	Document-Execution

457
 458 In the following we describe, for each of the table entries above, how the user and/or a tool
 459 provider will make use of the metamodel, and how each of the other pieces of the ebXML
 460 architecture are related.

461
 462 For ease of understanding, we divide this discussion into the following distinct types of
 463 scenarios.

464 ‘From Scratch design’ – An organization designing, implementing, registering a brand new
 465 market and process.

466 ‘Conversion’ – An organization converting an existing market and process design, and adjusting
 467 an existing implementation.

468 “Discovery and adaption” – An organization discovering an existing partner and process and
 469 adapting their existing implementation to interoperate.

470 “Actual communication” – Two organizations actually conducting business by exchanging
 471 messages.

472
 473 **Brand new business model.**

474
 475 This scenario assumes for simplicity that none of the parts of the business model are yet in the
 476 repository and that the organization(s) designing it are willing to retrofit their applications to fit
 477 the new model.

478
 479 The stages the organization would go through are:

480 .. When this is working they would register the market, party, partner-role, business process,
 481 information exchange and business documents and register themselves as capable of supporting
 482 this new model.

- 483
 484
 485 1. Design: (For the organization would either use established modeling tools and convert the
 486 output to DTD/XML compliant with the ebXML metamodel, or they would use newer
 487 lightweight ebXML front end tools to produce ebXML compliant DTD/XML directly)
 488 a) Market-Design: Determine and describe the market in terms of its domain and it’s
 489 parties.

- 490 b) Process-Design: Determine and describe the business process in terms of its
491 partner roles and business transactions
492 c) Exchange-Design: Determine and describe each business transaction in terms of
493 its required messages exchanged.
494 d) Document-Design: Determine and describe each business document in terms of
495 its attributes
496
497 2. Implementation. (This may be accomplished using new lightweight adaptor tools to front-
498 end their applications)
499 a) Market implementation is not relevant
500 b) Process-Implementation: Design and implement a Business Process Service that
501 covers all the business transactions specified in 1.b. above.
502 c) Exchange-Implementation: Design and implement Information Exchange
503 Handlers that cover all the Information Exchanges specified in 1.c. above.
504 d) Document-Implementation: Design and implement mappings from the documents
505 specified in 1.d. above.
506
507 3. Registration: Registration takes place by using a web-based front end to the ebXML
508 repository and/or sending a model compliant xml file using the ebXML message
509 exchange.
510 a) Market-Registration: Register each market and party specified in 1.a.
511 b) Process-Registration: Register business process specified in 1.b. and its associated
512 business transactions and business rules.
513 c) Exchange-Registration: Register for each business transaction specified in 1.b. the
514 required information exchanges as specified in 1.c.
515 d) Document-Registration: Register each business document specified in 1.d. above.
516

517 The process and site-implementation for this “brand new” business process is now ready for
518 business, next step would be “discovery and adaptation” by potential business partners (see
519 below)
520

521 **Conversion**

522

523 This scenario assumes for simplicity that the company already has a complete model design
524 described in some other format and protocol.
525

526 The stages the organization would go through are:

- 527
528 1. Design. (or in this case convert the existing explicit or implicit design)
529 a) Market-Design: Extract and convert from existing model the market in terms of
530 its domain and it’s parties. This conversion should yield an ebXML metamodel
531 compliant XML based model ready for registration.
532 b) Process-Design: Extract and convert from existing model the business process in
533 terms of its partner roles and business transactions. This conversion should yield
534 an ebXML metamodel compliant XML based model ready for registration.

- 535 c) Exchange-Design: Extract and convert from existing model each business
536 transaction in terms of its required messages exchanged. This conversion should
537 yield an ebXML metamodel compliant XML based model ready for registration.
538 d) Document-Design: Extract and convert from existing model each business
539 document in terms of its attributes. Since many “libraries” of standard based
540 document designs already exist, and since the metamodel here is very flexible, it
541 is anticipated that little or no conversion be needed for standards based
542 documents. Rather there would just be a qualification attribute of the exchange-
543 design in 1.c. above as to which of several standards the documents involved
544 belong to.
545
- 546 2. Implementation. (This may be an activity of creating wrappers around the existing system
547 to enable the sending and receiving of messages).
548 a) Market implementation is not relevant
549 b) Process-Implementation: Design and implement a Business Process Service that
550 covers all the business transactions specified in 1.b. above.
551 c) Exchange-Implementation: Design and implement Information Exchange
552 Handlers that cover all the Information Exchanges specified in 1.c. above.
553 d) Document-Implementation: Design and implement mappings from the documents
554 specified in 1.d. above.
555
- 556 3. Registration: Registration takes place by using a web-based front end to the ebXML
557 repository and/or sending a model compliant xml file using the ebXML message
558 exchange.
559 a) Market-Registration: Register each market and party specified in 1.a.
560 b) Process-Registration: Register business process specified in 1.b. and its associated
561 business transactions and business rules.
562 c) Exchange-Registration: Register for each business transaction specified in 1.b. the
563 required information exchanges as specified in 1.c.
564 d) Document-Registration: Register each business document specified in 1.d. above.
565 Since your document may already be specified in another industry standard
566 protocol, you may register just a hyper-link to where the specification is found in
567 an ebXML compliant format.
568

569 The process and site-implementation for this “converted” business process is now ready for
570 business, next step would be “discovery and adaptation” by potential business partners (see
571 below)
572

573 **Discovery and adaption**

574

575 This scenario assumes for simplicity that an organization can find a partner with an appropriate
576 process and only needs to make adjustments to its applications in order to ‘play’. In this scenario
577 the discovery comes first (so we have changed the sequence, but left the numberings intact as a
578 reference back to the matrix). Once discovery has yielded an acceptable partner, process,
579 information exchange, and document structure, the organization has only to adapt its
580 applications.

581
582
583

The stages the organization would go through are:

4. Discovery: (This is done using web front ends to the ebXML repository, or by sending XML ‘query’ documents through the ebXML message facility).
 - a) Market-Discovery: Using appropriate keywords and wildcards find the market of interest. Starting from the market find possible parties who may be possible partners.
 - b) Process-Discovery: Starting from each possible partner discover his/her role in various processes. Find a process that matches the business transactions you need to transact.
 - c) Exchange-Discovery: Starting from each business transaction discover if you are capable of producing and consuming the required information exchanges in the specified protocols.
 - d) Document-Discovery: Starting from each information exchange, discover if you are capable of mapping into and out of the specified business documents.

1. Design. Not applicable, in essence this organization is using a design already done by another organization.
 - a. Market design was discovered in 4.a. above
 - b. Process design was discovered in 4.b. above
 - c. Exchange design was discovered in 4.c. above
 - d. Document design was discovered in 4.d. above

2. Implementation. (This may be an activity of creating wrappers around the existing system to enable the sending and receiving of messages).
 - a. Market implementation is not relevant
 - b. Process-Implementation: Design and implement a Business Process Service that covers all the business transactions specified in 1.b. above.
 - c. Exchange-Implementation: Design and implement Information Exchange Handlers that cover all the Information Exchanges specified in 1.c. above.
 - d. Document-Implementation: Design and implement mappings from the documents specified in 1.d. above.

3. Registration: Not required unless you want to establish a more formal ‘trading partner agreement’
 - a. Market registration already done
 - b. Process registration already done
 - c. Exchange design may involve the registration of your business process interface to handle your end of the process. This may be validated against the business processes already registered for handling the other end.
 - d. Document registration may involve the registration of your document handler interfaces to handle the incoming and outgoing messages. At this point it may be possible to send a series of “test messages” that traverses the whole process and proves that the two parties can in fact live up to the implicit or explicit ‘trading partner agreement’.

627 Note: The described kind of registration of business process interfaces and document
628 handler interfaces may not initially be part of ebXML scope, rather – initially - an eCO
629 style self-registration on your own site might be workable.
630

631 This business partner is now ready to do business with the partner/process previously registered.
632

633 **Actual communication**

634

635 This scenario assumes that we have already designed, registered and implemented as per above.
636

- 637 1. Design: Already done above
- 638 2. Implementation: Already done above
- 639 3. Discovery: Already done above
- 640 4. Registration: Already done above
- 641 5. Execution: The model drives the execution in the sense that the business transaction
642 sequence within a process is (optionally) specified, and the message exchange sequence
643 within a business transaction is (optionally) specified. So one could envision an
644 implementation that actually accesses the ebXML repository to figure out what needs to
645 happen next. More likely the parties implement their ebXML process compliant message
646 handlers, and the exchanges happen directly between these message handlers, using
647 message formats prescribed in the repository. These message handlers may themselves
648 handle the mapping into or out of the organizations applications, or may interact with
649 “wrappers” specifically designed for this purpose. In either case, the ebXML end of the
650 mapping is prescribed by the registered documents.

Automobile Component Procurement Example

655

Introduction

657

658

659 This is the first ebXML-BP metamodel example. More will come, including some that are much
660 simpler than this one, which is deliberately complex in order to test the metamodel.

661

662 This example is not "final". The intention is for this example to develop along with the ebXML
663 project until it is fully populated with functional test data, and also to be accompanied by several
664 other examples illustrating different scenarios.

665

666 The reasons for starting with this particular process include:

- 667 • it is a supply chain component procurement example, instead of the usual office supply
668 purchase;
- 669 • the business practices cover most of the metamodel;
- 670 • the business practices are well documented by an industry-wide group, AIAG (Automotive
671 Industry Action Group);and
- 672 • the business practices are similar to supply chain relationships in other industries, e.g.
673 appliances and retail.

746 **Auto Supply Chain Procurement Practices Not Captured in Current Use**
747 **Cases**

- 748
- 749 1. **Preliminary trading partner agreements** may be formed before contracts are negotiated.
750 These agreements may not carry any economic commitments. They would be mapped to the
751 Agreement class in the latest ebXML metamodel.
752
 - 753 2. **Intermediate consignees** may be used in the Delivery use case, to pool components before
754 delivery to the point of production, and/or to perform outside services.
755
 - 756 3. **Variations in delivery authorization** include regular purchase orders, delivery schedules,
757 sequenced delivery schedules, and electronic Kanbans or JIT pull signals.
758
 - 759 4. **Variations in payment authorization** include evaluated receipts settlement, pay on
760 production, pay to the ASN, and invoices.
761
 - 762 5. **Variations in payment**

Metamodel Design Issues

These are places where the use cases do not map cleanly to the current ebXML metamodel classes and relationships.

1. There are several missing relationships in the **Contract Formation Step 1** collaboration diagram:
 - 1.1. Recursive relationship from [**Business Process Definition**] to nested [**Business Process Definition**].
 - 1.2. Recursive relationship from [**Economic Resource Type**] to subcomponent [**Economic Resource Type**] (e.g. Bill of Materials relationships and Tools).
 - 1.3. Relationships between higher and lower level [**Economic Resource Types**] (e.g. Component Family and Component Master).
 - 1.4. Relationships from [**Economic Resource Types**] to [**Information Entities**] (e.g. Specifications).
2. It is clear that [**Agreement Types**], [**Agreements**] and [**Contracts**] are complex objects. Likewise [**Economic Resource Types**]. Should their decomposition be part of the metamodel, or deferred to Common Components? (Same issue applies to any other complex objects.)
3. The relationships between [**Information Entities**] and other metamodel classes are not specified in the metamodel.
